

# Trade Liberalization and the Informal-Formal Job Ladder

Cristhian Seminario-Amez

October, 2020

# Quasi-Experiment: Informality and Transitional Dynamics

- ▶ How does the availability of informal contracts affect **transitional dynamics in response to a large negative shock**?

I exploit two well-documented features for Brazil:

1. **Heterogeneous enforcement of labor regulations** across municipalities: Almeida and Carneiro (2012), Ulyssea and Ponczek (2018).
2. **Unilateral trade liberalization** episode: Dix-Carneiro and Kovak (2017, 2019), Ulyssea and Ponczek (2018).

# The trade liberalization episode in Brazil (1/2)

Between 1990 and 1995, the **average import tariff in Brazil went from 30.5 to 12.8 percent**; remaining stable afterwards. Correlation between tariff changes and pre-liberalization levels  $\sim -0.90$  [D-C & K (2017)].

Source: D-C & K (2017). Industries sorted based on 1991 national employment.

# The trade liberalization episode in Brazil (2/2)

- From D-C & K (2017), measures of **labor demand shocks at the micro-region** level induced by trade liberalization.

$$\underbrace{RTR_r}_{\text{Regional Tariff Reductions}} = - \sum_i \underbrace{\beta_{ri}}_{\text{Regional Weights based on Industry Mix}} \underbrace{d \ln(1 + \tau_i)}_{\text{Tariff Change for Industry } i \text{ between 1990-1995}}, \quad \beta_{ri} = \frac{\lambda_{ri} \frac{1}{\gamma_i}}{\sum_j \lambda_{rj} \frac{1}{\gamma_j}}$$

where  $\gamma_i$  denotes the cost share of nonlabor factors in industry  $i$ , and  $\lambda_{ri}$  the initial share of local employment of industry  $i$  in region  $r$ .

- **In words:** the higher the initial share of local employment in industries that experienced large tariff declines, the larger the negative shock on labor demand.

# Enforcement heterogeneity across regions in Brazil

- ▶ Compliance is monitored through surprise visits to firms. “Inspectors are assigned to enforcement offices located in cities across Brazil. They choose which firms to visit ... [and] travel by car from their base city to the city where the inspected firm is located ... [They] face a performance-based pay scheme .. up to 45 percent of their wage is tied to the efficiency of the overall enforcement system [and] their monthly base wage is fairly competitive (between 2,490 and 3,289 dollars in 2004)” [Almeida and Carneiro (2012)].
- ▶ Motivated by this, previous work has instrumented the probability of being inspected with **the distance of a firm’s municipality to the closest enforcement office** [e.g. Almeida and Carneiro (2012), Ulyssea and Ponczek (2018)].

# Preliminary empirical exercise

- ▶ **Today:** Based on the distances computed by Almeida and Carneiro (2012), I divide municipalities **in each state** in two groups: those **closer** than the **state-median** municipality ( $l_{far} = 0$ ) and those **farther away** ( $l_{far} = 1$ ) 
- ▶ Consider the following regression, at the municipality-level, run separately for each  $t = \{1992, \dots, 2017\}$

$$\underbrace{y_{mt} - y_{m1991}}_{\text{Change in Labor Market Outcome Variable}} = \alpha + \gamma_t \underbrace{RTR_{r(m)}}_{\text{Regional Tariff Reductions}} + \phi_t l_{far} + \beta_t RTR_{r(m)} \times l_{far} + \underbrace{\theta_{s(m)t}}_{\text{State FE}} + \delta_t \underbrace{(y_{m1990} - y_{m1986})}_{\text{Pre-Liberalization Trend}} + \epsilon_{mt}$$

where  $m$  indexes municipalities, and  $r(m)$  and  $s(m)$  the corresponding micro-regions and states. Similar to Dix-Carneiro and Kovak (2017).

# Regional Earnings in Formal sector

- ▶ Ulyssea and Ponczek (2018): between 1991 and 2000, regions with **weaker** [stricter] enforcement observed **a significant** [no] increase in informal employment but **no** [significant] non-employment effects, among unskilled workers, in response to the trade liberalization shock.
- ▶ If indeed **informal jobs facilitate the transition of workers across rungs of the job ladder**: in the long run, weaker enforcement can be associated with better outcomes in the formal sector too  $\implies$  **Today**: Earnings.
- ▶ **Data**: employer-employee matched annual **administrative data** from Brazilian RAIS for the **1986-2017** period.
- ▶ **Earnings premia at the municipality level**: I run, for each  $t = \{1986, \dots, 2017\}$ , the following worker-level regression

$$\underbrace{y_{it}}_{\text{Worker's Log Monthly Real Earnings}} = \underbrace{y_{m(i)t}}_{\text{Municipality FE}} + \underbrace{X_{it}}_{\text{Sex, Age and Education Groups Dummies}} \eta_t + \zeta_{it}$$

municipality FE  $y_{m(i)t}$  is the measure of earnings premia.

# Descriptive Stats

	$I_{far} = 0$				$I_{far} = 1$			
Variable	Mean	SD	P25	P75	Mean	SD	P25	P75
Distance (minutes)	47	32	27	63	130	74	85	153

DSC	-0.0 (-0.4)	-0.0 (-1.6)	-0.0* (-1.7)	-0.0 (-0.9)
$\text{RTR} \times \text{DSC}$	0.0 (0.3)	0.1** (2.2)	0.2*** (2.7)	0.2** (2.3)
N	2620	2620	2620	2620
Adj. $R^2$	0.187	0.471	0.573	0.607

t stats in parentheses; "DSC" is the Distance to State Capital (i.e. a control); All regressions include state FE.

## Effect of TL shock on Formal Earnings Premia by $I_{far} = \{0, 1\}$

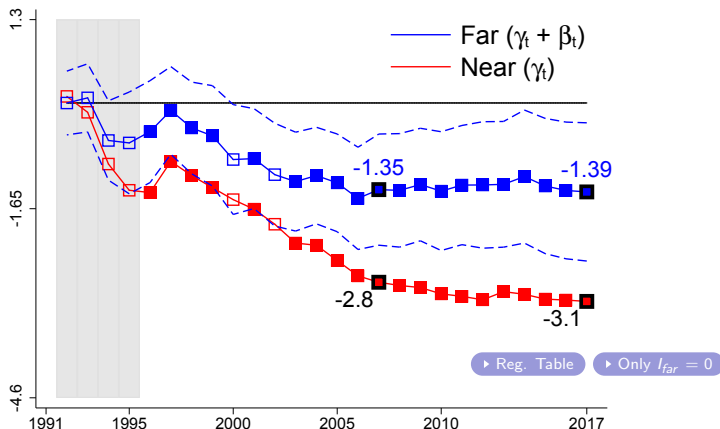

Among local labor markets **near** to an enforcement office: **an increase of 10 p.p. in RTR** (i.e. our negative shock measure) induces, **by 2017**, an average decrease of **26 p.p.** in the cumulative growth rate of formal earnings premia.

## Effect of TL shock on Formal Earnings Premia by $I_{far} = \{0, 1\}$

Among local labor markets **far** from an enforcement office: **an increase of 10 p.p. in RTR** (i.e. our negative shock measure) induces, **by 2017**, an average decrease of **13 p.p.** in the cumulative growth rate of formal earnings premia.

# Effect of TL shock on Earnings Premia [Young] by $I_{far} = \{0, 1\}$

Considering only the cohort of workers that were **less than 30 years-old** by 1991: the **gap between both groups increases**.

# Robustness Checks

**Main concern:** according to the descriptive stats, “**weak enforcement**” municipalities experienced **SMALLER** negative TL shocks.

So far, three pieces of evidence suggest this is **NOT** what drives our results:

1. The coefficient for the  $I_{far}$  dummy in our main regression is **not significant**.

► Main Reg. Table

2. Conditional on controls, the observation is reversed: “weak enforcement” municipalities experienced **LARGER** negative TL shocks. Important to control for **distance to state capital** (DSC). ► RTR *conditional densities*

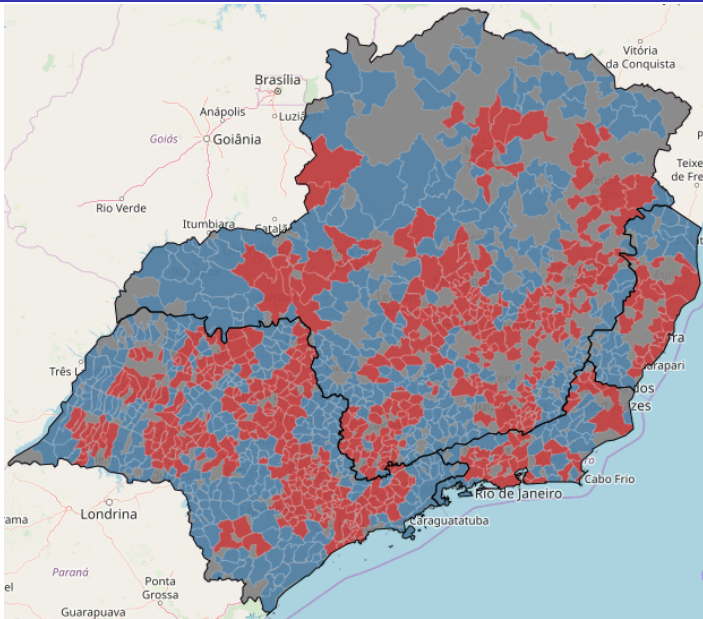

3. Running our main regression considering only **municipality pairs** (one from each enforcement group) **with comparable RTR shocks**, the main effect ( $\beta_t$ ) remains significant. ► Main Figure - paired municipalities ► RTR densities - paired municipalities
